

Three Roads: Choose Your Stack with AI

Chosen Stack:

Static HTML/CSS + Datawrapper embeds

Reason:

I built the risk-list analysis in Python and the dashboard in Power BI. For the portfolio site, I didn't embed the Power BI dashboard as-is. I pulled the one or two charts that actually prove the point, rebuilt them in Datawrapper, and themed them to match my site — ink, warm white, one red accent for risk flags. Everything else is plain HTML and CSS.

Alternatives:

I looked at two other options first.

The simplest was embedding the Power BI dashboard directly with its "Publish to web" export. Zero extra work. But Power BI's own styling would sit inside my site like a foreign object. The whole point of the design is that it looks considered, not templated. A stock BI embed breaks that on sight.

The most powerful was turning the analysis into a live Streamlit app, so someone could actually filter and sort the risk list themselves. That's a real demo, not a picture of one. But it means running and maintaining a second free service indefinitely, and cold-start lag on a first click is a bad first impression. My data isn't dynamic — the risk list for this project doesn't change week to week — so I don't need a live tool to make the point. I need to show the reasoning clearly.

Reason:

Data wrapper gets me that: charts that look like they belong on my site, no JS to write, and nothing extra to maintain once they're live. I can build it in two weeks with the skills I already have. The one thing I'm giving up is literal interactivity — a viewer sees curated evidence of the tool, not the tool itself. For this deliverable, showing the judgment behind the list matters more than letting someone click around in it, so that trade is fine.
