Configured Claude Project:

Pressure-test prompt and Output:

Prompt:

Here's my sitemap: Landing (states claim + CTA) → Flagship project page (the request, the method, the deliverable, caveats, CTA again) → optional short "other work" footnote → CTA.

Pressure-test this against my claim ("I turn subscription billing and usage data into a weekly list of exactly which customers to contact before they cancel") and my one action (they message me on LinkedIn). For each page, tell me: does it move someone closer to that one action, or is it decoration? Where would a skeptical, busy analyst stop trusting me or get distracted? What's the single weakest link in the path from landing to messaging me?

Output:

Straight pressure test, page by page.

Landing page — moves toward the action, but only if it resists a specific temptation. It's one job is: state the claim, show one visible proof point, point at the project. The place a skeptical analyst stops trusting you here is if the landing page tries to *sell* instead of *state* — hype words like "passionate," "results-driven," a big headshot, a mission statement. A busy overloaded person reads that as noise and bounces before reaching the project. It moves someone closer to the action only if it gets out of the way in under 10 seconds. Right now, without seeing actual copy, I can't confirm it does — the structure is right, the execution risk is real.

Flagship project page — this is where the claim either gets proven or dies. It's the whole game. It moves someone closer to the action *only if* it's structured in the order you listed: request → method → deliverable → caveats. If you flip that order — method-first, deliverable buried at the bottom — a skeptical analyst stops trusting you almost immediately, because you'll look like you're proving you *did data science* rather than proving you can *answer their question*. They don't care about your feature engineering until they've seen the list.

The second place trust breaks on this page: **caveats**. If you skip them, a sharp analyst assumes you don't know your model's limits — which is disqualifying for someone they'd trust unsupervised. If you over-hedge with five caveats, you look unsure of your own work. One or two honest, specific caveats ("this assumes at least 90 days of usage history," "flags risk, doesn't rank urgency") is the trust-building zone.

"Other work" footnote — decoration, and mildly risky decoration. It doesn't move anyone toward the action. Its only job is to not *subtract* trust. The failure mode: if the other work is unrelated (a scraper, a Kaggle notebook, a dashboard for a different domain), it dilutes the one-thing-I-do-well positioning you spent nine

questions building. If you include it, it should be one line, demoted, ideally still subscription/data-adjacent — not a gallery.

CTA — the weakest link is here, and it's not the button itself, it's the trigger before it.

Here's the honest answer to your actual question: **the single weakest link in the whole path is the gap between "I'm impressed by this analysis" and "I trust this specific person enough to message them."** A skeptical analyst can read a clean methodology, see a clean weekly list, and still not click "message" — because nothing on the page told them *what happens after they message you*. Right now your CTA says "message me to start the hiring conversation," but that's still slightly abstract. The drop-off risk is: they finish the project, think "nice work," and then... close the tab, because messaging a stranger on LinkedIn who might turn into a slow, awkward exchange feels like more effort than it's worth.

The fix isn't a new page — it's specificity in the CTA copy itself: tell them exactly what they get by messaging you (e.g., "Message me and I'll walk you through how I'd adapt this to your churn signals" or "Message me — I'll send you the notebook and answer any question about the method in 24 hours"). That converts "message me" from a vague social ask into a concrete, low-effort next step with a named payoff. Without that, your sitemap is structurally sound but the last three feet of the path — the actual moment of clicking — is the weakest link.
