Case: Churn Risk — Weekly Contact List

The problem

I had the Telco customer dataset from Kaggle and asked it straight questions: how many customers churned, what the churn rate was, whether it was tied to contract type, gender, being a senior citizen, revenue, tenure. Most of it confirmed the obvious. But contract type didn't.

What I did and decided

Churn was highest among month-to-month customers, by a wide margin over one-year and two-year contracts. That was the thread worth pulling. I dug into tenure, average charges, and internet service type for that group and found a specific pattern: short tenure (0–1 years), higher-than-average charges, paying by electronic check, on fiber optic internet. I built a Power BI dashboard around it — filterable by gender, contract, payment method, and internet service, with a live customer table underneath.

Then I looked at the dashboard and saw the gap. It told me which segments churn more. It didn't tell me who to call. A chart isn't a list. So I turned the same five factors into a simple point-based risk score, checked it against real churn outcomes in the data first, and applied it to customers who hadn't churned yet — ranking them into "call this week," "call this month," and "monitor."

What came of it

The score held up: customers scoring 0 churned 1% of the time historically, customers scoring 9 churned 71% of the time. Applied to the 5,174 still-active customers in the dataset, it produced a ranked list of 287 people to contact this week, each with a plain reason attached — not just a score.

It's a Kaggle dataset, not a live company's billing system. But the thinking — question, pattern, dashboard, gap, fix — is real, and it's mine.

What I'd do differently next time: build the scored, ranked list from the start, instead of stopping at the dashboard and only noticing the gap afterward.

Before / After

Generic AI line (before): "I am a passionate, results-driven data analyst dedicated to turning data into actionable insights that drive business success."

Edited (after, my voice): "I turn subscription billing and usage data into a weekly list of exactly which customers to contact before they cancel."

The before line could describe anyone, for any company, doing anything. The after line only describes this — a specific output, for a specific person, from a specific kind of data.

Bio

I turn subscription billing and usage data into a weekly list of exactly which customers to contact before they cancel. Built for data analysts at small startups who don't have time to turn "who's at risk" into a real answer themselves.
